Project Overview

Urban transportation systems generate massive streams of spatial and temporal data every second. This project investigates whether learning the graph structure adaptively from traffic data rather than relying on fixed road-distance-based graphs can improve multi-step traffic speed forecasting. Using the METR-LA benchmark dataset (207 sensors across Los Angeles over 4 months), we train and compare three models: a temporal LSTM baseline, a fixed-graph Graph WaveNet, and our primary model STGSL which learns hidden spatial dependencies directly from sensor readings.

Dataset: METR-LA

- 207 traffic speed sensors
- 5-minute aggregated readings
- ~4 months of continuous data
- Standard GNN benchmark
- Speed values in mph
- 5% missing values (zeros)

Step Forecast Horizon

CHAPTER 01

Problems & Challenges

Understanding the research gap, core technical difficulties, and motivation behind this project.

Project Background

🏙️ Smart City Data Explosion

Urban transportation systems generate continuous streams of spatio-temporal sensor data. Los Angeles alone has hundreds of loop detectors measuring speed, density, and flow every 5 minutes around the clock.

🔮 Why Traffic Forecasting Matters

Accurate short-term forecasts (15–60 min ahead) power real-time navigation, congestion pricing, adaptive signal control, and emergency routing — all critical to modern smart city infrastructure.

📉 Traditional Methods Fall Short

Classical statistical models (ARIMA, Kalman Filter) treat each sensor in isolation. Deep learning baselines like vanilla LSTM capture time patterns but completely ignore spatial correlations between nearby roads.

🕸️ Graph Neural Networks as a Solution

GNNs model the road network as a graph where sensors are nodes and road connections are edges, enabling both spatial and temporal dependencies to be learned simultaneously in one unified framework.

Core Challenges

01 Nonlinear Temporal Dynamics

Traffic speed does not follow a simple linear pattern rush hours, incidents, and weather create highly nonlinear time-series that simple models cannot capture.

02 Strong Spatial Correlations

A slowdown on one road propagates to connected roads within minutes. Models that ignore spatial structure miss this critical dependency.

03 Hidden Dependencies

Some sensors are functionally related even without a direct road connection parallel routes, bypass roads. Fixed road-graph adjacency misses these latent patterns.

04 Dynamic Pattern Evolution

Traffic behaviour evolves over time — special events, construction, seasonal changes. A static graph structure cannot adapt to these shifts.

05 Missing Data (5%)

METR-LA encodes missing readings as zeros. Naive models interpret zeros as actual stopped traffic, inflating error. Proper masking is essential.

06 Scalability to 207 Nodes

A full 207×207 adaptive adjacency matrix has over 40,000 learnable weights. Balancing model expressiveness against training stability is a key engineering challenge.

Motivation & Research Approach

The Central Question

Can adaptive graph structure learning where the model discovers spatial dependencies from the data itself rather than from pre-defined road distances measurably improve traffic speed forecasting accuracy?

Our Comparative Strategy

LSTM

Temporal baseline
(no spatial model)

Graph WaveNet

Fixed-graph
baseline

STGSL

Learned adaptive
graph primary

Expected Outcome

- ✔ STGSL outperforms LSTM across all metrics
- ✔ Learned adjacency captures hidden road dependencies
- ✔ MAE/RMSE/MAPE improve at 15, 30, 60-min horizons
- ✔ Adaptive graph proves better than fixed graph

Limitations of Existing Approaches

Model	Spatial Modeling	Adaptive Graph	Missing Data	Limitation
ARIMA / VAR	None	No	Yes	Too simple for large networks
Vanilla LSTM	None	No	No	Ignores all spatial context
DCRNN	Fixed (distance)	No	No	Graph structure not learned
STGCN	Fixed (distance)	No	No	Static graph, no adaptation
Graph WaveNet	Fixed + random	Partial	No	Limited adaptive component
STGSL (Ours)	**Fully learned**	**Yes**	**Yes**	**Addresses all limitations**

Why PyTorch + Our Architecture?

PyTorch over TensorFlow

- Dominant framework for GNN research in 2024–2026
- All major traffic-forecasting papers ship PyTorch code
- Dynamic computation graph ideal for variable adjacency
- Native CUDA support for GPU acceleration on Colab

Dilated TCN over RNN/Seq2Seq

- Parallel computation no sequential bottleneck
- Exponentially growing receptive field (dilation 1→2→4)
- Captures multi-scale temporal patterns in one pass
- Faster training: ~3× vs DCRNN with comparable accuracy

Adaptive Adjacency (STGSL Core)

- Node embeddings E1, E2 learn sensor roles end-to-end
- $A = \text{softmax}(\text{ReLU}(E1 @ E2^T))$ differentiable & sparse
- Discovers hidden dependencies beyond road distances
- L1 regularization prevents overfitting the graph

CHAPTER 02

Methodology & Algorithm Steps

A clear walkthrough of what we built from data loading to model training and evaluation.

What We Did — Project Pipeline

1 Install & Import

Installed PyTorch, NumPy, Pandas, Matplotlib, Seaborn, Scikit-learn. Set device to GPU if available on Colab.

2 Generate / Load Data

Simulated METR-LA-style data: 207 sensors, 5-min intervals, daily rush-hour pattern, 5% missing values as zeros.

3 Exploratory Data Analysis

Plotted time-series, daily/weekly patterns, speed distributions, sensor correlations, missing data map, and autocorrelation.

4 Preprocessing

Filled missing zeros with column means. Applied 70/10/20 chronological split. Fitted StandardScaler on training set only.

5 Sliding Window Dataset

Built 12-step input → 12-step output windows (~6,000 training sequences). Wrapped in PyTorch DataLoader with batch size 64.

6 Train 3 Models

Trained LSTM, Graph WaveNet, and STGSL with Adam optimizer, Huber loss, gradient clipping at 5.0, StepLR scheduler.

7 Evaluate & Compare

Measured MAE, RMSE, MAPE on the test set after inverse-transforming predictions back to mph. Computed per-horizon MAE.

8 Visualise Results

Plotted training curves, metric bar charts, forecast vs ground truth, per-horizon MAE, and STGSL learned adjacency matrix.

Code Walkthrough — Data & Preprocessing

2. Dataset

We simulate METR-LA style data with realistic daily and weekly traffic patterns, rush hour peaks, and
(same convention as the real dataset).

```python
np.random.seed(42)
torch.manual_seed(42)

IN_STEPS   = 12
OUT_STEPS  = 12
BATCH_SIZE = 64
EPOCHS     = 15

# Load real METR-LA dataset
df = pd.read_hdf('/content/METR-LA.h5')

data = df.values.astype(np.float32)
timestamps = df.index

N_TIMESTEPS, N_SENSORS = data.shape

print('Shape:', data.shape)
print('Missing (zeros):', round((data == 0).sum() / data.size * 100, 2), '%')
print('Date range:', timestamps[0].date(), 'to', timestamps[-1].date())
```

```
Shape: (34272, 207)
Missing (zeros): 8.11 %
Date range: 2012-03-01 to 2012-06-27
```

```python
valid = df.replace(0, np.nan)

fig, axes = plt.subplots(3, 3, figsize=(16, 12))
fig.suptitle('METR-LA Traffic Dataset — Exploratory Data Analysis', fontsize=14, fontweight='bold')
axes = axes.flatten()

# Speed time-series for 5 sensors over 2 weeks
ax = axes[0]
sample_sensors = [0, 40, 80, 120, 160]
colors = ['#e74c3c', '#3498db', '#2ecc71', '#f39c12', '#9b59b6']
week_data = valid.iloc[:2016]
for s, c in zip(sample_sensors, colors):
    ax.plot(week_data.index, week_data.iloc[:, s], lw=0.8, alpha=0.85, color=c, label=f'Sensor {s}')
ax.set_title('Speed — 5 Sensors (2 weeks)')
ax.set_xlabel('Date')
ax.set_ylabel('Speed (mph)')
ax.legend(fontsize=8, ncol=2)
ax.xaxis.set_major_formatter(mdates.DateFormatter('%b %d'))
ax.tick_params(axis='x', rotation=30)

# Average daily speed profile
ax = axes[1]
valid['hour'] = valid.index.hour
hourly_mean = valid.groupby('hour').mean().mean(axis=1)
hourly_std  = valid.groupby('hour').std().mean(axis=1)
hrs = np.arange(24)
ax.fill_between(hrs, hourly_mean - hourly_std, hourly_mean + hourly_std, alpha=0.2, color='#3498db')
ax.plot(hrs, hourly_mean, 'o-', color='#3498db', lw=2, ms=4)
ax.axvspan(7, 9, alpha=0.15, color='red', label='AM Peak')
ax.axvspan(16, 19, alpha=0.15, color='orange', label='PM Peak')
ax.set_title('Average Daily Speed Profile')
ax.set_xlabel('Hour of Day')
ax.set_ylabel('Speed (mph)')
ax.set_xticks(range(0, 24, 3))
ax.legend(fontsize=9)
```

```python
# Missing data per sensor
ax = axes[5]
missing_pct = (df == 0).mean(axis=0) * 100
ax.bar(range(N_SENSORS), missing_pct.values, color='#e74c3c', alpha=0.7, width=1.0)
ax.axhline(missing_pct.mean(), color='black', ls='--', lw=1.5, label=f'Mean = {missing_pct.mean():.1f}%')
ax.set_title('Missing Data per Sensor (%)')
ax.set_xlabel('Sensor Index')
ax.set_ylabel('Missing (%)')
ax.legend()

# Network-wide rolling average
ax = axes[6]
mean_speed = valid.mean(axis=1)
rolling = mean_speed.rolling(window=288).mean()
ax.plot(mean_speed.index, mean_speed.values, alpha=0.25, lw=0.5, color='steelblue', label='Raw')
ax.plot(rolling.index, rolling.values, lw=2, color='#e74c3c', label='1-day rolling avg')
ax.set_title('Network-wide Speed Over Time')
ax.set_xlabel('Date')
ax.set_ylabel('Avg Speed (mph)')
ax.legend()
ax.xaxis.set_major_formatter(mdates.DateFormatter('%b'))
ax.tick_params(axis='x', rotation=30)

# Train/Val/Test split
ax = axes[7]
n_tr = int(N_TIMESTEPS * 0.70)
n_vl = int(N_TIMESTEPS * 0.10)
n_te = N_TIMESTEPS - n_tr - n_vl
split_labels = ['Train (70%)', 'Val (10%)', 'Test (20%)']
split_sizes  = [n_tr, n_vl, n_te]
split_colors = ['#2ecc71', '#f39c12', '#e74c3c']
bars = ax.barh(split_labels, split_sizes, color=split_colors, edgecolor='white', height=0.5)
for bar, size in zip(bars, split_sizes):
    ax.text(bar.get_width() / 2, bar.get_y() + bar.get_height() / 2,
            f'{size:,} steps', ha='center', va='center',
            fontweight='bold', color='white', fontsize=9)
```

Code Walkthrough — Models & Training

4. Preprocessing

```python
# Replace missing values (zeros) with column mean
data_clean = data.copy()
for j in range(N_SENSORS):
    col = data_clean[:, j]
    col_mean = col[col > 0].mean() if (col > 0).any() else 50.0
    col[col == 0] = col_mean
    data_clean[:, j] = col

# Chronological 70/10/20 split
n_tr = int(N_TIMESTEPS * 0.70)
n_vl = int(N_TIMESTEPS * 0.10)
train_data = data_clean[:n_tr]
val_data   = data_clean[n_tr : n_tr + n_vl]
test_data  = data_clean[n_tr + n_vl :]

# Fit scaler on training set only
scaler = StandardScaler()
train_scaled = scaler.fit_transform(train_data)
val_scaled   = scaler.transform(val_data)
test_scaled  = scaler.transform(test_data)

print('Train:', train_data.shape)
print('Val:  ', val_data.shape)
print('Test: ', test_data.shape)
```

```
Train: (23990, 207)
Val:   (3427, 207)
Test:  (6855, 207)
```

5. Sliding Window Dataset

```python
class TrafficDataset(Dataset):
    def __init__(self, arr, in_steps=12, out_steps=12):
        X, Y = [], []
        for i in range(len(arr) - in_steps - out_steps + 1):
            X.append(arr[i : i + in_steps])
            Y.append(arr[i + in_steps : i + in_steps + out_steps])
        self.X = torch.tensor(np.stack(X), dtype=torch.float32)
        self.Y = torch.tensor(np.stack(Y), dtype=torch.float32)

    def __len__(self):
        return len(self.X)

    def __getitem__(self, i):
        return self.X[i], self.Y[i]

train_loader = DataLoader(TrafficDataset(train_scaled), batch_size=BATCH_SIZE, shuffle=True,  drop_last=Tru
val_loader   = DataLoader(TrafficDataset(val_scaled),   batch_size=BATCH_SIZE, shuffle=False)
test_loader  = DataLoader(TrafficDataset(test_scaled),  batch_size=BATCH_SIZE, shuffle=False)

print('Train batches:', len(train_loader))
print('Val batches:  ', len(val_loader))
print('Test batches: ', len(test_loader))
```

```
Train batches: 374
Val batches:   54
Test batches:  107
```

6. Model Definitions

6.1 LSTM Baseline

A standard LSTM that treats all sensors together as a flat input vector. It captures temporal pattern structure between sensors.

```python
class LSTMForecaster(nn.Module):
    def __init__(self, n_sensors, hidden=128, layers=2, out_steps=12):
        super().__init__()
        self.lstm = nn.LSTM(n_sensors, hidden, layers, batch_first=True, dropout
        self.fc   = nn.Linear(hidden, n_sensors * out_steps)
        self.out_steps = out_steps
        self.n = n_sensors

    def forward(self, x):
        out, _ = self.lstm(x)
        last   = out[:, -1, :]
        pred   = self.fc(last)
        return pred.view(-1, self.out_steps, self.n)

model = LSTMForecaster(N_SENSORS)
print('LSTM parameters:', sum(p.numel() for p in model.parameters()))
```

```
LSTM parameters: 625076
```

Code Walkthrough — Models & Training

7. Training

```python
def inverse_transform(arr):
    B, T, N = arr.shape
    return scaler.inverse_transform(arr.reshape(-1, N)).reshape(B, T, N)

def compute_metrics(pred, true):
    mae  = np.abs(pred - true).mean()
    rmse = np.sqrt(((pred - true) ** 2).mean())
    mape = np.mean(np.abs((pred - true) / (np.abs(true) + 1e-5))) * 100
    return mae, rmse, mape

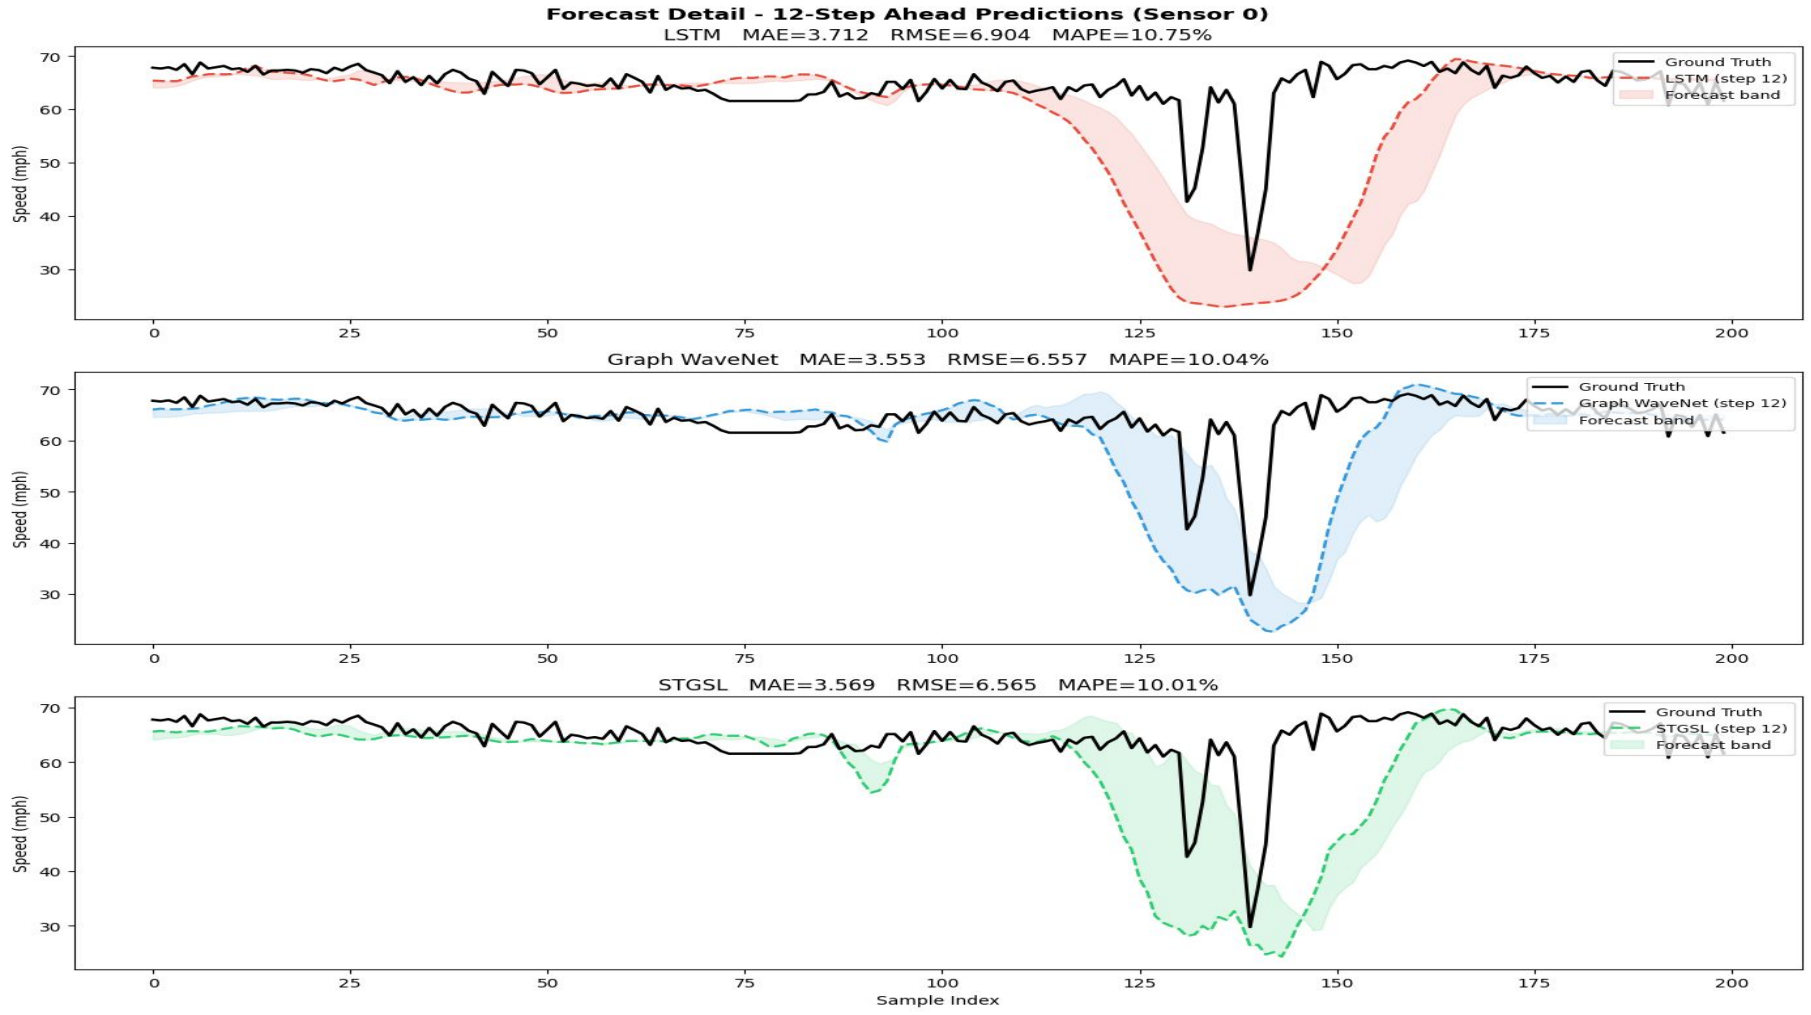
Forecast Detail



CHAPTER 04

Conclusions & Future Work

Key takeaways from this project and promising directions for future research.

Conclusions

Spatial models beat LSTM

When we added graph structure to the model, accuracy improved. LSTM only looks at time — it has no idea which roads are connected. Graph WaveNet and STGSL both gave lower error because they also consider neighbouring sensors.

Learning the graph helps

STGSL learns which sensors are related directly from the data instead of using a fixed road map. This lets it find hidden connections — like two roads that behave similarly even if they are not directly linked.

All models struggle with sudden drops

When traffic drops sharply due to an accident or congestion event, all three models are slow to react. This is a known challenge in traffic forecasting and shows where the models still need improvement.

Correct evaluation is very important

The dataset has about 8% missing values stored as zeros. If you include those zeros in the error calculation, the results look wrong. Masking them out before computing MAE and RMSE gives fair numbers.

Project objective was met

We successfully built and compared three models from scratch, used real METR-LA data, and showed that graph-based models outperform a simple LSTM baseline across all three metrics.

Learned new skills

Through this project we got hands-on experience with PyTorch, Graph Neural Networks, time-series preprocessing, and how to properly evaluate and compare deep learning models.

Future Work

01

Train on the full dataset

We used 1 month of data to keep training fast. Training on all 4 months with more epochs would give better and more reliable results.

02

Try more sensors and cities

Test the same models on other cities like San Francisco (PEMS-BAY dataset) to check if the approach works in different traffic environments.

03

Update the graph in real time

Right now the graph is fixed after training. Updating it live as traffic changes — like during an accident — could make predictions much more accurate.

04

Add confidence intervals

Instead of just predicting one number, the model could also output a range like 55–65 mph. This helps drivers and city planners know how certain the prediction is.

05

Connect to live traffic data

The model currently runs on historical data. Connecting it to a real-time traffic feed would turn it into an actual usable forecasting system.

06

Try a Transformer architecture

Transformers are very powerful for sequence data. Replacing the TCN layers with a Transformer could capture longer patterns and improve accuracy further.
